

The Submissions Book

Seven strategies have been proposed for capital. Each page is one submission as it reached the validation desk: the researcher's note, the registry entry, the claimed performance, and the equity curve. The full trade blotters and the market data accompany this book.

At least one of these is honest. The rest are broken in ways that have each cost real trading desks real money. Your job, as one team, is to build an automated validation report: a pipeline that takes any submission's records and returns a verdict — PASS, SUSPECT with conditions attached, or FAIL — with the evidence behind every line, so a head of trading could act on it. The same pipeline runs over all seven submissions. The truth — and the future — are unsealed at the reveal.

Everything you may use: this book, the trade blotters, the market data tables, and the registry metadata. You will not receive source code.

WINDFALL

wind-revision drift

“The intraday market underreacts to wind forecast revisions. One weather run revises the whole day; the price response completes over the following 15–45 minutes rather than instantly. We trade the direction of the latest revision whenever its price implication exceeds ~2 EUR/MWh — a tradeable revision arrives roughly every other day — at a fixed 10 MW clip, exiting as the signal decays. Edge per trade comfortably exceeds typical spreads. The edge has softened somewhat in recent months, which we attribute to the market getting faster; we believe it remains comfortably tradeable.”

Backtest window	2025-01-01 – 2026-06-30 (546 days)	Avg win / avg loss (day)	182 / -35 EUR
Total P&L (10 MW clip)	34,951 EUR	Best / worst day	1,943 / -445 EUR
Sharpe (ann.)	5.98	Max drawdown	-445 EUR
Sortino (ann.)	14.17	Avg volume	44 MW/day
Active days	46%	Net margin	1.45 EUR/MWh traded
Hit rate (active days)	80%		

WINDFALL 2.0

wind-revision drift · upgraded data

“Windfall's economics, upgraded data. Through a trial with a new forecast provider we obtain materially fuller vintage coverage — in effect, we see revisions earlier and more completely than the public feed. The trading framework is identical to Windfall's (same thresholded revision signal, same 10 MW clip, same hysteresis exits); the improvement is entirely in the input. The backtest speaks for itself, with a hit rate that reflects the quality of the vintage data. We propose running it alongside Windfall, funded at twice the clip.”

params {enter: 4.0, decay: 0.5} · declared trials: 8 · data dependency: WeatherDesk Pro vintage feed (provider trial)

Backtest window	2025-05-27 – 2026-06-30 (400 days)	Avg win / avg loss (day)	452 / -120 EUR
Total P&L (10 MW clip)	102,137 EUR	Best / worst day	9,016 / -457 EUR
Sharpe (ann.)	6.87	Max drawdown	-457 EUR
Sortino (ann.)	21.67	Avg volume	58 MW/day
Active days	58%	Net margin	4.38 EUR/MWh traded
Hit rate (active days)	98%		

SUNSPOT

solar-revision drift

“The solar application of the revision framework behind Windfall: cloud-cover forecast updates are priced sluggishly, particularly in the shoulder hours where solar sets the marginal unit. Same thresholded signal, same 10 MW clip, daylight products only. H1 2026 has been flat — we attribute this to an unusually stable forecast regime this spring, and expect normal performance as convective season returns. We propose funding at the same clip as Windfall.”

Hit rate (active days)	81%		

SPIKECATCHER

fleet-stress optionality

“When margin is thin, the intraday market underprices the right tail. We build an hourly exposure score from announced planned unavailability plus forecast residual-load tightness, and go long a fixed 10 MW in the top 5% of exposed delivery hours, four hours before gate, held to close. The day-ahead auction charges a premium for announced outage risk — but we believe it under-charges for the convexity: when one more unit trips on a stressed day, the move is violent. Most active days we bleed the premium; the spike days pay for everything.”

Hit rate (active days)	51%		

PINGPONG

passive dislocation capture

“Short-horizon liquidity provision. Intraday prices oscillate around a slow-moving anchor; when a product’s mid dislocates by more than the noise floor but less than a news-sized move, we fade it for one 15-minute interval. We execute passively, resting orders inside the spread. High frequency, small per-trade edge, large N. We propose scaling by product count.”

params {thresh: 0.65, band: 1.2, span: 0.5} · declared trials: 15

Backtest window	2025-10-24 – 2026-06-30 (250 days)	Avg win / avg loss (day)	768 / -606 EUR

Active days	100%	Net margin	0.12 EUR/MWh traded
Hit rate (active days)	77%		

BOUNCEBACK

asymmetric spike reversion

“Downward overreactions revert; upward moves are physical. When oversupply or a ramp resolution knocks a product more than 5.5 EUR down inside an hour, the move systematically overshoots — sellers hit whatever bids exist — and partially retraces. Scarcity-driven up-moves reflect real shortage and persist, so we fade the downside only. Entry on the trigger, hold 45 minutes. Six months of live-market observation preceded the backtest; the rule has three parameters and we deliberately kept it simple.”

Hit rate (active days)	50%		

BLACKBOX

cross-signal momentum ensemble

“A machine-learned ensemble over 42 intraday features — order-book imbalance, revision momentum, calendar effects, cross-hour flow — trained to emit one direction per product per session, entered at open and held to gate. The features are individually weak; the edge is emergent, and we accept that the model is not fully interpretable — the backtest is the argument. Model 371 is the production candidate from our runs registry. We retrain monthly and expect live performance to track the backtest.”

params {model_id: 371, n_features: 42} · declared trials: 3 (architecture variants) · retrained monthly
